# Overview

This code, protomidpy (Reconstruction of Protoplanetary Disk on Mid-plane in Python), implements an analytical framework for deriving the surface brightness profile and geometry of a geometrically-thin axisymmetric disc from interferometric observation of continuum emission, as proposed in Aizawa et al. (2024). A unique feature of this code is that it allows posterior sampling for all parameters, including the brightness distribution a, geometric parameters g, and hyperparameters for the Gaussian Process  $\theta$  (see Fig. 1.1):

$$p(\boldsymbol{a}, \boldsymbol{g}, \boldsymbol{\theta} | \boldsymbol{d}) \tag{1.1}$$

With the precise determination of these parameters, we can discuss faint signals possibly embedded in proto-planetary disks. Additionally, there is no need to tune hyperparameters, making the inference highly objective. This work can be seen as a natural extension of the previous work by Jennings et al. (2020), which solves for a while fixing  $(g, \theta)$ . Their code (frank) or frankenstein) is available at https://github.com/discsim/frank.

The installation and requirements are summarized in Chapter 2. Parameters files, which are prepared in the params folder, are detailed in Chapter 3. After setting the parameters, scripts can be run to realize the posterior distribution, as described in Chapter 4.

The author does not take any responsibility for any problems that the code may cause, so please use it at your own risk. If you have any questions or suggestions, please contact me (aizw.masa@gmail.com).

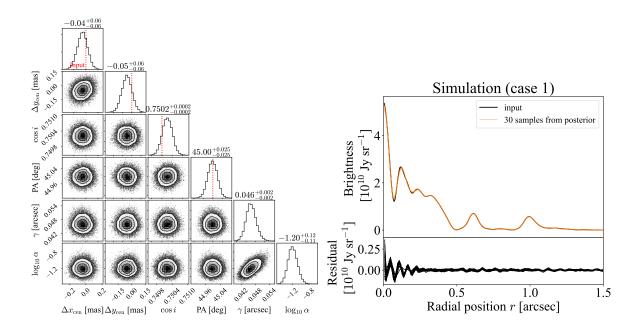

Figure 1.1: Example for posterior sampling for all of disc parameters. The figure is taken Aizawa et al. (2024) (Fig. 2 in the paper)

# Install & Requirements

#### 2.1 Install

pip install ./georadial

### 2.2 Requirements

- $\bullet$  astropy
- emcee
- $\bullet$  corner
- $\bullet$  matplotlib
- numpy
- $\bullet$  scipy
- pandas
- Jupyter notebook

# Prepare for configuration files

#### 3.1 Format of input data

The data must be in form of ".npz" in numpy, and it needs to contain following items:

• u\_obs: Spatial frequency "u" [lambda]

 $\bullet$  **v\_obs**: Spatial frequency "v" [lambda]

• vis\_obs: Visibility

• wgt\_obs: Weights

Download test data from https://github.com/2ndmk2/dsharp\_averaged\_data for reference.

### 3.2 Config files

We have three config files for running code.

#### MCMC setting (example: params/mcmc\_config.dat)

Parameters for emcee and model

#### • Nrad

Number of radial points for model intensity

#### • Nhin

Determine grid size for log-binning. Grid size is (2\*Nbin+1, 2\*Nbin+1).

#### • Dpix

Radial spacing for model [arcsec].

Outer disk radius is determined as Rout = Nrad \* Dpix

#### • Nwalker

Number of walkers for emcee

#### Nchain

Number of chains for emcee

#### • out\_folder

Path to output folder

#### Initial position for walkers (example: params/AS209\_paradic.dat)

Parameters determining initial positions for mcmc. They are randomly generated with uniform distribution [value-scatter/2, value+scatter/2].

#### Prior distribution (example: params/prior.dat)

Parameters for determining ranges of priors:

- Regularization parameter  $\log \alpha$ Uniform prior,  $[\log_{10} \alpha_{\min}, \log_{10} \alpha_{\max}]$
- Central position for disk Uniform prior, [-delta\_pos [arcsec], delta\_pos [arcsec]]

# Run scripts

### 4.1 Run MCMC (example: tests/run\_sampling.py)

#### 4.1.1 Overview

With emcee (Foreman-Mackey et al., 2013), we take samples from posterior distribution for  $p(\mathbf{g}, \boldsymbol{\theta} | \mathbf{d})$  given as:

$$p(\boldsymbol{g}, \boldsymbol{\theta}|\boldsymbol{d}) \propto \mathcal{N}(\boldsymbol{d} \mid \boldsymbol{0}, \bar{\boldsymbol{\Sigma}}_d + \bar{\boldsymbol{H}} \boldsymbol{\Sigma}_a \bar{\boldsymbol{H}}^T) p(\boldsymbol{g}, \boldsymbol{\theta}),$$
 (4.1)

#### 4.1.2 Example command

python run\_sampling.py --n\_process 4 --visfile ./vis\_data/
AS209\_continuum\_averaged.vis.npz --config ./paras/mcmc\_config.dat
--initial\_para ./paras/AS209\_paradic.dat --prior ./paras/prior.dat

The options are given as follows:

- $\bullet$  **n\_process**: Number of CPU cores to be used in emcee.
- **visfile**: Path to visibility file (3.1)
- config: path to mcmc config file (3.2).
- initial para: path to mcmc config file (3.2).
- **prior**: path to mcmc config file (3.2).

### 4.2 Postprocess Calculation (example: tests/model\_calc.py)

#### 4.2.1 Overview

Using samples from  $p(\mathbf{g}, \boldsymbol{\theta} \mid \mathbf{d})$ , we take sample from full posterior,

$$p(\boldsymbol{a}, \boldsymbol{g}, \boldsymbol{\theta} | \boldsymbol{d}) = p(\boldsymbol{a} | \boldsymbol{d}, \boldsymbol{g}, \boldsymbol{\theta}) p(\boldsymbol{g}, \boldsymbol{\theta} | \boldsymbol{d}), \tag{4.2}$$

and model visibilities:

$$\begin{pmatrix} V_{\text{real}} \\ V_{\text{imag}} \end{pmatrix} = \begin{pmatrix} C_{\text{real}} H' \\ C_{\text{imag}} H' \end{pmatrix} a, \tag{4.3}$$

where  $H', C_{\text{real}}$ , and  $C_{\text{imag}}$  are defined as follows:

$$\{\boldsymbol{H'}\}_{j,k} = \frac{4\pi R_{\text{out}}^2}{j_{0(N+1)}^2 J_1^2(j_{0k})} J_0(2\pi q_j r_k), \qquad (4.4)$$

(4.5)

$$\{C_{\text{real}}\}_{j,k} = |\cos i|\cos(-2\pi(\Delta x_{\text{cen}}u_j + \Delta y_{\text{cen}}v_j))\delta_{j,k},$$

$$\{\boldsymbol{C}_{\text{imag}}\}_{j,k} = |\cos i|\sin(-2\pi(\Delta x_{\text{cen}}u_j + \Delta y_{\text{cen}}v_j))\delta_{j,k}.$$
(4.6)

#### 4.2.2 Example command

python model\_calc.py --n\_sample\_for\_rad 20 --n\_burnin 20000
--visfile ./vis\_data/AS209\_continuum\_averaged.vis.npz
--mcmc\_result\_file ./result/AS209\_continuum\_averaged.vis\_mcmc.npz
--initial\_para ./paras/AS209\_paradic.dat --prior ./paras/prior.dat
--out\_file\_for\_model ./result/AS209\_continuum\_averagedmodel.npz

The options are given as follows:

- n\_sample\_for\_rad: Number of samples for intensity profiles
- n\_burnin: Number of Burnin samples
- visfile: Path to visibility file
- mcmc\_result\_file: Path to result file from run\_sampling.py
- out\_file\_for\_model: Path to output file

### 4.3 Check result (tests/mcmc\_plotter.ipynb)

Run mcmc\_plotter.ipynb with Jupyter

- samplefile: Path to file for posterior sampling output from run\_sampling.py
- modelfile: Path to postprocess result from model\_calc.py
